**Introduction**

In 1913, Chevalier Jackson was the first to report a high rate of success for the use of direct laryngoscopy as a means to intubate the trachea \(^1\). Since the popularization of endotracheal intubation by Magill in 1934, it remains till date an integral and indispensable feature of the conduct of general anesthesia \(^2\).

Laryngoscopy is used to facilitate tracheal intubation under vision. Successful laryngoscopy depends on achieving a line of sight from the maxillary teeth to the larynx. The tongue and epiglottis are the anatomic structures that intrude into the line of sight. Management of the tongue and epiglottis is therefore central to successful direct laryngoscopy. Before the laryngoscope is inserted, the patient is normally placed in the “sniff” position. The direct laryngoscope is then used to displace the tongue and epiglottis out of the line of sight. The tongue is displaced horizontally (normally to the left) from the line of sight, the hyoid bone and attached tissues are moved anteriorly, and the epiglottis is elevated to reveal the larynx. The force applied to the laryngoscope handle should lift the hyoid bone and attached tissues parallel to the line of sight. Adequate lifting force is a key factor in successful direct laryngoscopy. It is important to achieve the best possible view of the larynx without causing tissue trauma. It is not always possible to achieve line of sight with direct laryngoscopy. The Macintosh curved laryngoscope is radically different from the preexisting straight laryngoscopes. In particular, the long axis of the blade is curved, the cross section is a right-angled “Z” section, the web and flange are bulky, the tip is atrumatic, and the light bulb is shielded by the web. The three component steps of direct laryngoscopy are insertion of the laryngoscope, adjustment of its position and lifting force, and use of other maneuvers to optimize the view of the glottis.
The “sniff” position is used. Full mouth opening facilitates insertion of the laryngoscope. It is inserted from the right side of mouth and to the right of the tongue while taking care to not trap the lips between the laryngoscope blade and the teeth. The laryngoscope is advanced and simultaneously moved into the midline to displace the tongue to the left. Progressive visualization of anatomic structures minimizes the risk of trauma. The epiglottis is the first key anatomic landmark. The tip of the laryngoscope is advanced into the vallecula, and the epiglottis is elevated indirectly by applying a force that tensions the hyoepiglottic ligament. Elevation of the epiglottis is optimized and a further lifting force is applied to the laryngoscope to achieve the best view of the larynx. It is very important not to lever on the maxillary teeth because this may cause dental damage and reduce the view of the larynx. When a good view of the larynx is achieved, the vocal cords, aryepiglottic folds, posterior cartilage, and interarytenoid notch can be identified. This technique has some hemodynamic effects. Introducing tube through nasal passage also has different effects as nasotracheal intubation can evoke the nasocardiac reflex, which depresses the tachycardic response. So we conducted the study to observe haemodynamic response in nasotracheal intubation under general anaesthesia using direct laryngoscope.

Aims and objective
To observe haemodynamic response in nasotracheal intubation under general anaesthesia using direct laryngoscope in 50 ASA grade I and II patients for elective surgery under general anaesthesia requiring endotracheal intubation with respect to
- Haemodynamic changes during intubation.
- Haemodynamic changes at the time of & after intubation.
- Time required for intubation.
- Saturation.
- Post extubation epistaxis.
- Mean arterial pressure.

Materials and methods
The study was conducted at Rajindra Hospital, Patiala in 50 patients, aged 18 to 60 yrs of ASA grade I and II scheduled to undergo elective surgery under general anaesthesia requiring intubation.

Inclusion criteria
- ASA I and II
- Age 18 to 60 yrs
- BMI of 30 or less
- No diagnosed chronic medical disease

Exclusion criteria
- Patient’s refusal
- Patients with an anticipated difficult airway
- Obesity
- Cardiovascular and Endocrine disease
- On drugs known to produce changes in heart rate and blood pressure like beta blockers, digitalis, calcium channel blockers, oral contraceptives.
- Bleeding disorders
- History of nasal surgery or trauma

Nasal polyp

A written informed consent was obtained from each patient after explaining the technique prior to inclusion in this study in their own vernacular language.

Preanaesthetic checkup was done in every patient. All patients received Inj Glycopyrolate (0.2mg) I.V, Inj Midazolam (2mg) iv + Inj Promethazine (25mg) IM as premedication 30 min before the elective surgery. Fifteen minutes before shifting the patient to the OT table, in both the nasal passages 0.1% Oxymetazoline nasal drops were instilled. All patients received Tab. Alprazolam 0.25 mg 1 HS and 6 am on the day of surgery.

Method
The study was conducted in 50 patients of either gender aged 18 to 60 years belonging to ASA I and II scheduled for elective surgery.

After the patient is brought to operation table baseline measurements of heart rate, blood pressure and Spo2 were taken. Fentanyl in a dose of 1.5 μg/kg were administered intravenously 5 minutes before induction. Patients were preoxygenated with 100% O2 for 3 minutes. General anaesthesia was induced with an intravenous injection of propofol, 2mg/kg and intubation was facilitated with the use of rocuronium 0.9 mg/kg intravenously. Then patient were ventilated with 100% oxygen. Intubation was commenced exactly after 90 seconds of giving inj.rocuronium. Nasotracheal intubation was carried out with the aid of laryngoscope. A 7.00 mm internal diameter, cuffed endotracheal tube (ETT) was used for female patients and 7.5 mm internal diameter cuffed ETT for male patients. The ETT was advanced into the trachea over the scope After introduction of ETT, anaesthesia was maintained with O2:N2O:40:60 along with 0.8-1.5% isoflurane. The following parameters were observed: heart rate (HR), systolic blood pressure (SBP), diastolic blood pressure (DBP) and mean arterial blood pressure (MAP). These parameters were recorded at following time intervals: baseline value, after induction, at the time of insertion of laryngoscope, immediately after intubation and thereafter at 3, 5 and 10 minutes. ECG and SPO2 were monitored continuously as per the intervals mentioned above. The study was terminated at the end of 10 minutes after intubation. However, vitals were monitored throughout the surgery. Time of intubation from cessation of mask ventilation to connection of breathing circuit to ETT was noted. And postintubation epistaxis if any was noted.

Observations
The mean age was 37.04 yrs and male to female ratio was 6:44. with mean weight being 59.08 Kg.

Spo2 was continuously monitored during intubation and it was found that patients maintained 100% saturation during induction, at the time of insertion of direct laryngoscope, at 3min, 5min and 10 min. 8 patients had lower reading immediately after intubation with mean SpO2 of 99.96%. Mean time for intubation using laryngoscope was 18.2 sec. Epistaxis was seen in2 of 50 patients i.e.4%.

Haemodynamic parameters are tabulated and depicted in graphs.

Table shows that Baseline HR, SBP, DBP and MAP were 82.72±16.83 bpm, 122.04±14.67 mmHg, 79.6±18.77 mmHg and 93.75±15.68 mmHg (mean±2sd) respectively. Maximum readings of all parameters were noted at the time of insertion of DLS. There was significant fall of all parameters after induction comparing with baseline (p<0.0001).

There was significant fall of all parameters after induction.

Discussion

Mean age of the patients in study was 37.04yrs, male to female ratio was 3:22 and mean weight was 59.08 Kg. Epistaxis was seen in 2 of 50 patients i.e. 4% using DLS. It depends on proper preparation of patients. SpO2 was continuously monitored during nasotracheal intubation technique and it was found that patients maintained 100% saturation during induction, at 3 min, 5 min and 10 min. The mean SpO2 of the patient was 99.96%.

Mean time for intubation was 18.2 sec. Our findings were consistent with most of the studies conducted[^3, 6, 10, 14, 18].

Fig 1: Haemodynamic changes
comparing with baseline (p<0.0001) in all patients, there was no significant difference. This is due to the effect of anaesthetic agents used for induction. This finding is consistent with most of the studies conducted\textsuperscript{[3, 6, 10, 14, 18]}. The addition of fentanyl usually decreases the postintubation hypertension but can increase the propofol-induced pre-intubation hypotension\textsuperscript{[18]}. At the time of insertion of DLS there was significant rise of HR, SBP, DBP & MAP. This increase is due to stress response to laryngoscopy\textsuperscript{[10]}. During conventional laryngoscopy, the maximum force transmitted by a laryngoscope blade onto the base of the tongue is said to be as high as approximately 40 Newtons, and this stimulation is considered to be exceptionally invasive\textsuperscript{[9]}.

HR, SBP, DBP & MAP remained high after intubation but didn’t increase and returned to baseline value at 3min. Maximum readings of all parameters were noted at the time of insertion of DLS. In all patients HR, SBP, DBP and MAP was at baseline level at 3min. This finding is consistent with most studies.\textsuperscript{[7, 10, 12, 13, 16]}

In all patients HR, SBP, DBP and MAP was below baseline at 5min and 10min. This is due to effect of anaesthetic agents used for maintenance of anaesthesia. This finding is consistent with most other studies\textsuperscript{[7, 10, 12, 13, 16]}. There was significant high Haemodynamic response to laryngoscopy at the time of intubation which may be due to sudden severe stress response to DLS during intubation and also due to oropharyngeal and nasopharyngeal structures stimulation\textsuperscript{[3, 6, 8, 9, 10, 11, 12, 13, 15, 17]}.

Conclusion

Nasotracheal intubation under general anaesthesia has significant Haemodynamic effect.
